

Arkansas Game and Fish Commission Aerial Waterfowl Survey Report

January 15-20, 2016

January 2016 Survey Summary

Arkansas Game and Fish Commission biologists conducted aerial waterfowl surveys Jan. 15 in the Arkansas River Valley (ARV), Jan. 18 in southwest Arkansas and an abbreviated survey Jan. 18-20, 2016 in the Mississippi Alluvial Valley (MAV or Delta). The Delta the duck population index was just under a million ducks, including slightly over 600,000 mallards (Table 1). Observers counted about 20,000 ducks in southwest Arkansas, almost 15,000 of which were mallards (Table 2). Population estimates in the ARV were slightly over 34,000 and 47,000 for mallards and all ducks, respectively (Table 2). Biologist observers were Jason Carbaugh, Jason Jackson, J.J. Abernathy, Mike Harris and Alex Zachary.

Duck population estimates were nearly unchanged since the 2016 Midwinter Waterfowl Survey (MWS) and remain below average. The Delta mallard estimate was well below the long-term average, declining slightly from the 2016 MWS estimate (Figure 1). Southwest Arkansas counts were in line with typical counts for mallards and total ducks (Table 2). In contrast, the mallard population estimate in the ARV rose slightly after a substantial increase from December 2015 to the 2016 MWS (Table 2). Duck (Figure 2) and mallard (Figure 3) distribution across the Delta showed few concentration areas, while mallard and all duck distribution shifted noticeably eastward in the ARV (Figures 4 and 5).

One of the strangest waterfowl seasons in recent memories continues to lead to unpredictable and sometimes inexplicable patterns of duck abundance, or lack thereof. Despite extremely mild conditions throughout this wintering period this aerial survey was hampered by two rounds of wintry weather. Thus, this survey was not complete. Both the L'Anguille and Little River Ditches survey zones and portions of other survey zones were not flown so MAV-wide population indices likely are underestimates. Typically these two zones account for about 8% of the mallards in the MAV, so if they had about an average number of mallards this survey period the MAV mallard total might be closer to 715,000, still a relatively low count. Nonetheless, indices suggest relatively precise population estimates, so survey totals likely represent actual duck numbers as well as a complete survey would have.

Duck counts from neighboring states and weather data shed light on this year's duck migration. From the 2000s until present, Missouri counts typically peak around Thanksgiving, roughly following a bell curve. This year's migration into Missouri started later into November and peaked in December before falling. The peak was nearly two weeks later than normal and about the same number of ducks as the 5-year peak. Habitat conditions were wet in much of the state at least once, if not two or three times, this season leading to unusually high habitat availability. In Louisiana, the 1.85 million ducks estimated during the Midwinter Waterfowl Survey was only 70% of the December survey total of 2.64 million, only 55% of the January 2015 MWS total of 3.38 million, and about 39% lower than the most recent 5-year average of 2.97 million and the long-term average of 3.03 million. It is the lowest January estimate

since 2009's total of 1.59 million, the lowest on record for this survey. It is the 5th lowest January survey estimate, exceeding those of 1983, 1987, and 2008 as well as 2009. Also in Louisiana, the decline in ducks counted from December to January was even greater on the NE Louisiana survey (closest to the Arkansas portion of the Delta), where only 106,000 ducks and 88,000 geese were counted on selected habitats. That was less than a third of the 363,000 ducks and 199,000 geese counted in December. In Mississippi, December duck estimates increased from the previous survey period, and were similar to recent years' early January estimates. Estimates for mallards and diving ducks were also very similar to the long-term average for all early January surveys, but estimates for other dabbling ducks and overall ducks remained well below their long-term averages for early January. Estimates for all categories of ducks showed increases from the December survey.

Thanks to colleagues in each of these states for the above information.

This year's weather set records (<http://www.ncdc.noaa.gov/sotc/national/201512>; see figures below). The average contiguous U.S. temperature during December was 38.6°F, 6.0°F above the 20th century average. This was the warmest December on record for the Lower 48, besting the previous record of 37.7°F set in 1939. The average maximum (daytime) temperature was 48.1°F, 5.3°F above the 20th century average, the second highest maximum value on record behind 1939, and the average minimum temperature was 29.2°F, 6.6°F above average. Record warmth engulfed the eastern half of the nation, where 29 states had the warmest December on record. During December, there were 18.8 times more record warm daily maximum and minimum temperature records compared to cold daily maximum and minimum temperature records. The December precipitation total for the contiguous U.S. was 3.93 inches, 1.58 inches above the 20th century average, ranking as the wettest December on record. This surpassed the previous record of 3.76 inches set in 1982. In summary, December 2015 marks the only month in the 121-year period of record that holds the title of both warmest and wettest month on record. Clearly, this year has been far from "normal".

Table 1. Waterfowl abundance estimates in Arkansas during the late November (Nov), mid-December (Dec), early-January Midwinter Survey (MWS) and late-January (Jan) aerial waterfowl survey periods, 2009-2016, in the Mississippi Alluvial Valley (MAV) using stratified random sampling of transects.

Survey Design Background

The Mississippi Alluvial Valley is an area of continental significance for migrating and wintering waterfowl, as outlined in the North American Waterfowl Management Plan, and the single most important region for wintering mallards. Habitats found in western Arkansas, including the Arkansas River Valley and southwest Arkansas, such as the Red and Sulphur River floodplains, provide additional critical habitat for migrating and wintering waterfowl. Biologists conduct regular waterfowl surveys in these regions by aircraft up to four times each wintering period.

Winter waterfowl surveys, including the Midwinter Waterfowl Survey, have been conducted across much of the United States since 1935. Many different counting techniques have been used, and recently AGFC and partners have conducted surveys in the MAV using stratified random sampling of aerial fixed width (250m) strips, or transects, that have the advantages of extensive coverage (i.e., no area is excluded from the sample), increased accuracy by counting on fixed strips rather than traditional “cruise” surveys only counting waterfowl on large concentration areas, and availability of measures of sampling error.

Beginning in 2011 in the MAV, survey strata – or sampling zones – follow watershed boundaries (Figure 6). Watersheds in this case are simply land areas that are occupied by a drainage system consisting of a portion of a surface stream and all the tributary surface streams feeding it. For example, the Cache River strata includes lands surrounding and tributaries flowing into the Cache River from the Missouri border on the north to the Cache River’s junction with the White River on the south. At the root of this sampling design is the idea that habitat within these zones will share common weather and flooding patterns and, knowing that ducks are keyed in on such patterns, duck distribution will vary among watersheds. This is not a concept foreign to those who follow ducks, particularly duck hunters, as they frequently discuss habitat and duck numbers in terms of conditions in the “Cache River bottoms,” for instance. Systematically conducting aerial waterfowl surveys using this design will allow for more efficient allocation of sampling effort and provide precise estimates of waterfowl abundance in the MAV. Such a design offers an opportunity to track changes in abundance in response to changes in land use, flooding patterns or weather conditions, for example. A similar survey design was implemented beginning in Jan. 2013 in the Arkansas River Valley (Figure 7).

Before each survey period, transects to be flown are randomly selected within each strata. Biologists spend many hours in the air flying each of these transects – totaling over 3,500 miles each survey – recording all waterfowl observations using specialized computer software that collects location information in flight. Biologists also collect habitat information for each duck observation to track trends in habitat use. These data can then be used to generate population estimates for each strata and the entire MAV and develop visual representations of duck distribution (i.e., duck density maps).
